| Project Name  | Script-Controlled ACL - Restrict Record Access Based on Field Value |
| Maximum Marks | 2 Marks                                                             |

### Proposed Solution:

The proposed solution is based on the project documentation for a ServiceNow script-controlled ACL. The solution combines user roles with record field values to control record-level access.

| S.No. | Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.    | 1. Problem Statement (Problem to be solved) | Users may access institution records that they are not authorized to view or modify when access is controlled only by broad roles. A field-based access decision is required so that records are restricted according to the Branch value. In the project scenario, EEE users should access EEE records, while administrators retain full access. |
| 2.    | 2. Idea / Solution description              | Create the custom Institution Details table (u_institution_details), create the required users and roles, and configure Script-Controlled ACLs for READ, CREATE, WRITE, and DELETE operations. The READ ACL uses the Branch condition and script logic, while bb1, bb2, bb3, and bb4 provide progressive permissions.                             |
| 3.    | 3. Novelty / Uniqueness                     | The solution combines role-based authorization with a record field-value check in an ACL script. This makes access decisions specific to the data in each record instead of relying only on a user or role. The same approach can be demonstrated across multiple ACL operations.                                                                 |
| 4.    | 4. Social Impact / Customer Satisfaction    | The solution reduces the risk of unauthorized viewing, modification, creation, or deletion of records. It gives administrators clearer control over permissions and provides users with access only to records relevant to their authorized branch.                                                                                               |
| 5.    | 5. Business Model (Revenue Model)           | This project documentation does not define a direct revenue model. The solution is positioned as an internal enterprise security capability that can support organizations using ServiceNow by improving access governance and reducing manual permission handling.                                                                               |
| 6.    | 6. Scalability of the Solution              | The ACL approach can be extended to additional branches, fields, users, roles, tables, and access operations. New roles and field conditions can be added as requirements change, allowing the same security pattern to support larger ServiceNow implementations.                                                                                |
